A. Insert author with [name: string]	9
B. Update Add author [work_id: string, book_id: string, and inc works_count: int] using [_id: string]	10
C. Update author [about: string] using [_id: string]	12
D. Update author [gender: string] using [_id: string]	13
Description: Update or add gender info for an author.	13
E. Update author [imageurl: string] using [_id: string]	14
F. Delete Authors	16
G. List of Series [title: string] by author [name: string] (combining 2 tables)	17
H. Find authors who have an average rating in given range	18
I. Find image urls using [name: string]	19
J. Get all data of author using [_id: string]	20
K. Get authors with particular [gender: string]	21
L. Get author about info using [name: string]	22
M. Find authors with text_reviews_count in given range	23
N. Find authors with fans_count & ratings_count in given ranges	25
O. Find authors with works_count in given range	26

## **1. Team Members**

- Deep Shah
- Yunseo Han
- Dylan Lehuan Ha

## **2. Project Name**

- ALotOfAuthors

## **3. Project Description**

- ALotOfAuthors (ALOA) is a simple database application that lets you find, update, delete, and insert authors. ALOA could be used by libraries to manage books, keep track of authors and their ratings, and let people search for specific authors. The database stores documents of each author which consists of information such as author name, ratings, profile picture, about, gender, and number of fans. The dataset is relatively large with the total size being 1.8 gigabytes. The database was deployed in an AWS cluster of 7 nodes. There is one mongos server node, three config servers in a replica set, and three shard nodes, each of which have a replica set of 3 members. ALOA is written in Python, and has an end-to-end connection to the MongoDB database using pymongo. While using the application, the user can select from 15 different functions. After selection, the application gives instructions on making necessary inputs, which changes depending on the chosen function. After entering input, the ALOA will let the user know if their command was entered correctly and reject the input if any exceptions occur. The result from the command can be confirmed by checking the MongoDB database directly, which can be easily achieved by using a database GUI software like MongoDB Compass.

## **4. Project Successes**

- While implementing ALotOfAuthors, we successfully deployed a working MongoDB Database on AWS Elastic Compute Cloud (EC2). We then imported a 1.8 gigabyte dataset of authors and 230 megabytes of series into the cloud using MongoDB Compass, and connected it to a python application using pymongo. We then utilized MongoDB CRUD operations to create 15 different dynamic queries and commands that would be intuitive and practical in a library setting. Finally, we created a simple text GUI where users can interact with the database.
- This Project helped us understand the practical implications of NoSQL databases, their merits, and limitations. We also learned to effectively work as a team in a remote setting. It enabled us to work with the cloud platform AWS and learn more about cloud storage.
- We devised an efficient sharding setup that can ensure availability in case of node failure. To achieve this, we created 3 shards in one node with their replicas in the other 2 nodes. We then assigned higher priority to node 1 for shard 1, node 2 for shard 2, and node 3 for shard 3, so that all 3 shards have their primary replica in a different node. This will ensure efficient division of load and protection against failure.

## **5. Unexpected Events**

- We initially had difficulty in establishing an end-to-end connection from the server to our application. It was a critical step and after several efforts, we realized that there are some changes required in the

security group configuration. After changing the inbound connection rules, we were able to use the public DNS to connect the database with our application.

- While testing some queries for our application, we got errors for certain inputs. We realized that some documents were not in the correct format and were causing errors. We hence introduced error handling mechanisms to our application and made it dynamic to be able to handle variations in format.

## 6. Lessons Learned

- Important lessons learned were to create a complete application with efficient cloud storage. We learned the importance of horizontal scaling and also implemented it using AWS.
- Following improvements can be made:
  - improvements at the application level such as a better GUI
  - allowing several concurrent users
  - optimizing the server to be able to handle large number of requests from multiple users

## 7. DataSet

- <https://www.kaggle.com/datasets/opalskies/large-books-metadata-dataset-50-mill-entries>
- We used “authors.json” of size 1.8 gigabytes (original 3.35 gigabytes) and “series.json” of size 230 megabytes which are subsets of the “large-books-meta-dataset” and the authors.json has fields like name, books, gender, profile image, description, rating, about, and more required for our application.
- We first converted the files downloaded from Kaggle into an appropriate json format using sed commands to add commas and square brackets. We then used a json editor application to get only the required fields from authors.json and exported a part of it as a new authors.json file. We also changed the “id” field to “\_id” in both the files.

The image shows two side-by-side MongoDB Compass interfaces. The left interface is for the 'nosql\_project.authors' collection, displaying 3.5 million documents with a total size of 1.8GB. The right interface is for the 'nosql\_project.series' collection, displaying 226.7k documents with a total size of 230.3MB. Both interfaces show a list of documents with their IDs and some sample data. The 'Authors' collection includes fields like '\_id', 'name', 'books', 'fans\_count', and 'about'. The 'Series' collection includes fields like '\_id', 'title', 'description', 'note', 'series\_books\_count', 'primary\_work\_count', 'numbered', and 'works'.

Collection	Documents	Total Size	Avg. Size
nosql_project.authors	3.5m	1.8GB	509B
nosql_project.series	226.7k	230.3MB	1.0KB

Field	Type	Description
_id	String	Unique identifier for each document.
name	String	The author's name.
books	Object	Information about the author's books.
fans_count	Number	The number of fans.
about	String	A brief description of the author.
rating	Number	The average rating.
text_reviews_count	Number	The count of text reviews.
work_ids	Array	An array of book IDs.
works_count	Number	The count of works.
gender	String	The author's gender.
image_url	String	The URL of the author's profile image.

Field	Type	Description
_id	String	Unique identifier for each document.
title	String	The title of the series.
description	String	A description of the series.
note	String	A note about the series.
series_books_count	Number	The count of books in the series.
primary_work_count	Number	The count of primary works in the series.
numbered	Boolean	Indicates if the series is numbered.
works	Array	An array of book objects in the series.

## 8. Database Schema

- An “authors” collection is created. This collection contains authors along with all the information that describes the author. We also created a collection called “series” which contains book series as well as information such as series title, description, fans, and books within the series.

- Both “authors” and “series” collections have an “\_id” field which serves as the default index created by MongoDB. This \_id is unique and everytime a new author is populated, a unique \_id is added. This means that every single document has a unique \_id which allows it to be an index. It was also appropriate to have an index at \_id since it is used to search authors many times in update statements.
- We also added hashed indexes on each collection. A hashed index was added to the “name” field in the collection “authors”, and another was added to the “title” field in the “series” collection. We added these indexes so that we can search and access those fields quicker than the default which would look through every value in the collection.

## 9. NoSQL configuration

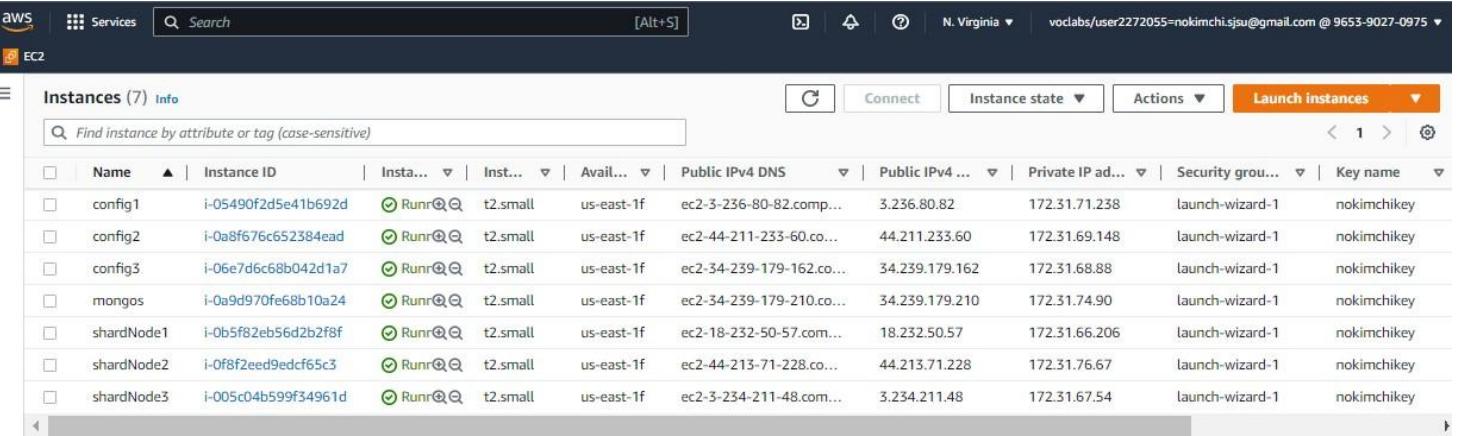

- To deploy ALotOfAuthors, we used Amazon Elastic Compute Cloud to create virtual machine Instances. With a total of 7 different instances, there is one mongos server, three config servers in a replica set, and three shard servers, each of which have a replica set of 3 members.
- To allow lower load per shard and protection against node failure, we created three shards in one node with their replicas in the other two nodes. We then assigned higher priority to node 1 for shard 1, node 2 for shard 2, and node 3 for shard 3, so that all three shards have their primary replica in a different node.

**Deployment Summary**

Service	Instance/ Node Name	IP Address (Private)	Port	Replica Set Name	Core Process	DB Path	Replica Priority
Shard Controller	mongos	172.31.80.79	27020	-	mongos	-	-

## Instances on AWS:

The screenshot shows the AWS Management Console with the EC2 service selected. The 'Instances' tab is active, displaying 7 running instances. The columns include Name, Instance ID, Status, Instance Type, Availability Zone, Public IPv4 DNS, Public IPv4 IP, Private IP address, Security Group, and Key Name. All instances are in the 'running' state.

	Name	Instance ID	Status	Instance Type	Availability Zone	Public IPv4 DNS	Public IPv4 IP	Private IP address	Security group	Key name

```

## 10. Shard Key & Sharding Strategy

- We have used hash based sharding on the field “name” for the Authors collection and on the field “title” for “Series” collection. These fields are the same as the one we previously added hashed indexes on. We chose to use “name” and “title” as shard keys because it can quickly fetch a document by searching for these fields, and using a monotonically increasing field like \_id would be a bad idea. However, names and titles can also have frequency issues with common names. For example, there may be a lot of authors with the name “John” which may lead to uneven chunks of data. That is why we chose to use hash based sharding that will make it random. “Name” and “title” are fitting to be a hash based shard key since it has high cardinality, meaning there are a large number of different values.

Shard status:

```

switched to db nosql_project
[direct: mongos] nosql_project> sh.status()

## 11. Connecting to the Application

- After setting up the mongos server, we changed the security group settings and added inbound network rules to allow external connections on port 27020 where the mongos server is running.
- We then used the public IPv4 DNS of the mongos node to create an end to end connection between the application and the database.
- We used pymongo as our NoSQL driver and created a connection using the command below:  
`myclient=pymongo.MongoClient("mongodb://ec2-3-235-20-235.compute-1.amazonaws.com:27020/test")`
- Once the connection is established, myclient variable can be used to select the database and access the required collections. Command to access DB: `db=myclient["nosql_project"]`
- Now using mongodb queries our application can send requests to the mongos server to update the documents in a database collection.

- Our application can also request to fetch data, in which case the mongos server with help of the config server will search through the shards, get the results and send it back to our application.

## 12. Running Queries on Data

For each function, we have attached the output of the python application and screenshots of MongoDB compass to clearly show that the function works.

### A. Insert author with [name: string]

Description: Can be used to insert a new document to the authors table.

Command: db.authors.insert\_one(indata)

### C. Update author [about: string] using [\_id: string]

Description: Update about info of an author. \_id needed as an update is a sensitive operation and needs to be unique in this case.

Command: db.authors.update\_one({"\_id": id}, {"\$set": {"about":newValue}})

(Before)

The screenshot shows a MongoDB document editor interface. On the left, there is a tree view of the document structure with nodes like '\_id', 'work\_ids', 'book\_ids', 'works\_count', 'name', 'gender', 'image\_url', 'about', and 'fans\_count'. On the right, the actual data values are displayed in a code-like format. At the top right, there are four icons: a pencil (edit), a lock (lock), a key (unlock), and a trash can (delete). The document content is as follows:

```
_id: "21"
ratings_count: 4
average_rating: 4.25
text_reviews_count: 0
work_ids: Array
  0: "1901236"
  1: "1111111"
book_ids: Array
  0: "1899579"
  1: "2222222"
works_count: 2

Author Name: Jude Fisher
["Fool's Gold", 'The Lord of the Rings: Visual Companion']
```

## (Example of series existing)

The screenshot shows the MongoDB Compass interface with the following details:

- Left Sidebar:** Shows databases: My Queries, Databases (with admin, config, nosql\_project, authors, and series selected). A search bar is also present.
- Header:** nosql\_project.series
- Header Buttons:** DOCUMENTS (highlighted), Aggregations, Schema, Explain Plan, Indexes, Validation.
- Header Metrics:** 226.7k DOCUMENTS, 2 INDEXES.
- Filter Bar:** Filtered by title: "The Lord of the Rings: Visual Companion".
- Action Buttons:** ADD DATA, EXPORT COLLECTION.
- Document Preview:** Shows a single document with the following fields:

```
_id: "202353"
title: "The Lord of the Rings: Visual Companion"
description: null
note: null
series_works_count: "4"
primary_work_count: "4"
numbered: "true"
works: Array
```
- Pagination:** 1-1 of 1.

## H. Find authors who have an average rating in given range

Description: To filter authors in a particular range of average ratings and get a certain limit of them.

Command: db.authors.find({"average\_rating": {"\$gte": minr, "\$lte": maxr}}, {"\_id":0, "name": 1, "average\_rating": 1}).limit(limit)

```
F. Delete author
G. List of Series [title: string] by author [name: string] (combining 2 tables)
H. Find authors who have an average rating in given range
I. Find image urls using [name: string]
J. Get all data of author using [_id: string]
K. Get authors with particular [gender: string]
L. Get author about info using [name: string]
M. Find authors with text_reviews_count in given range
N. Find authors with fans_count & ratings_count in given ranges
O. Find authors with works_count in given range

Author Name: *Marc R. Schloss*  
[[['21', 'This is a description about the author (test).']]

The screenshot shows a MongoDB document in a graphical interface. The document contains the following fields and their values:

- `_id: "21"`
- `ratings_count: 4`
- `average_rating: 4.25`
- `text_reviews_count: 0`
- `work_ids: Array` (with elements `0: "1901236"` and `1: "1111111"`)
- `book_ids: Array` (with elements `0: "1899579"` and `1: "2222222"`)
- `works_count: 2`
- `name: "Marc R. Schloss"`
- `gender: "male"`
- `image_url: "https://upload.wikimedia.org/wikipedia/commons/f/fa/Apple_logo_black.s..."`
- `about: "This is a description about the author (test)."`
- `fans_count: 4`

At the top right of the interface, there are four icons: a pencil (Edit), a copy symbol (Copy), a clipboard (Paste), and a trash can (Delete).

## M. Find authors with text\_reviews\_count in given range

Description: Find the authors who have number of text reviews in a given range

Command: db.authors.find({"text\_reviews\_count": {"\$gte": minr, "\$lte": maxr}}, {"\_id":0, "name": 1, "text\_reviews\_count": 1})

```
